Description

Lely Qwes

Insight into your cows' health prevents diseases and loss of production. The Lely Qwes cow-recognition system measures the most vital data per cow every two hours. There are tags for various aspects, such as identification, checking whether the cow is in heat and rumination.

Better reproduction

By accurately identifying the best insemination time, you increase the effectiveness of insemination. This also helps you to reduce calving intervals. The Qwes system is also available with heat detection. Lely T4C sends out a signal when the cow is in heat. This allows you to ensure that insemination happens at the right time.

Early warning of changes by monitoring rumination

Changes in rumination patterns are the first sign of potential problems. The Qwes system, which monitors rumination activity, alerts you to these. By linking these data to milk-yield information from the Lely Astronaut, the effect on cow performance and the dairy herd's appetite is monitored overall.
